Private Health Investments under Competing Risks: Evidence from Malaria Control in Senegal

Pauline ROSSI (UvA) and Paola VILLAR (PSE)

UNU-WIDER Seminar

October 18, 2017
Malaria has long been the leading cause of child death in Africa.

- 700,000 deaths in 2000.
- 25% of post-neonatal deaths.
- Perceived by parents as the main threat to children.
- First component of out-of-pocket health expenditures.

Recent large scale interventions to control the disease.

- Roll-Back Malaria partnership.
- High subsidies for anti-malaria products:
  - Preventive: Insecticide-Treated Nets (ITN)
  - Curative: Artemisinin-based Combination Therapy (ACT)
- Large impact on child survival (Cogneau and Rossi, 2017)
# Annual trends in infant mortality in Sub-Saharan Africa

The table presents estimates of the linear trend in child mortality before (1995-2001) and after the start (2002-2011) of anti-malaria campaigns for different populations: the richest half and poorest half of households (according to durable goods ownership) in regions with high and low initial malaria prevalence ($\geq 50\%$ or $< 50\%$ of children aged 2 to 10 are infected by the parasite).

We kept only children born at most 10 years before the survey to perform the estimation.

The last line reports the p-value of a test of equality between linear trends before and after 2002.

S.e. in (). $^* p \leq 0.1$, $^{**} p \leq 0.05$, $^{***} p \leq 0.01$. 
Does malaria prevent parental investment in child health?

Mechanism:
- Competing mortality risks generate a complementarity between different health investments.
- Malaria makes health investments unprofitable for the poor.
- Subsidies for anti-malaria products generate incentives to fight other causes of deaths.

Identification:
- Exploit the introduction of high subsidies in 2009 in Senegal.
- Examine changes in health-seeking behavior.
- Diff-in-diff using variation in initial prevalence of malaria.
What we do

- Develop a simple model of investment in health.
  - Adapt Dow et al (1999) to contexts with one prevailing disease.
  - Predict private responses to anti-malaria subsidies.
- Use original data from Senegal.
  - Panel data on household expenditures on child health.
  - Repeated cross-sections on child health status and health-seeking behavior.
  - Geographical data on malaria prevalence.
- Preview of results
  - Households raised their expenses to fight malaria and other diseases.
Contribution

- Provide empirical support to an economic model of health-seeking behavior.
  - So far, evidence based on data on health outcomes.
  - Plagued with omitted variable issues.
  - Direct test requires data on private expenses.
- Conceptual framework useful to:
  - Explain why poor people in insalubrious environments invest little in child health.
  - Predict how people respond to health subsidies.
Policy implications

- Policy debate: to give or not to give health products to the poor?
- Academic debate: are public and private health expenses complements or substitutes in the least developed countries?
- Anti-malaria campaigns have not crowded out parental health investments, quite the opposite.
- Helps explaining "one of the surprising results from large-scale trials of insecticide treated bednets is that the reduction in all-cause mortality is considerably greater than the reduction in malaria-attributed mortality" (Sachs and Malaney, 2002).
Outline

Model

Data

Empirical Strategy

Results

Robustness

Conclusion
Key theoretical insights

- Adapted from Dow, Philipson and Sala-i-Martin (AER, 1999).
- Trade-off between quantity and quality of life.
- Competing risks → Leontief function of production of survival → complementarity of disease-specific investments.
- Optimal allocation equalizes the lifetime across all causes of death.
Application to our context

- Predominance of malaria ⇒ corner solutions.
- 3 optimal allocations depending on wealth:
  1. No investment.
  2. Positive investment in malaria only.
  3. Positive investment in malaria and other diseases.
- Dramatic decrease in the price of anti-malaria treatments is predicted to raise private investments to fight malaria and other diseases.
From theory to data

- **Theory:** private investments in malaria and other diseases.
- **Data:** total household expenditures on child health and disease-specific health-seeking behavior.
- **Challenge:** disentangle quantities/prices and free/costly treatments.
- **Combine 3 predictions:**
  - P1 Total expenditures on child health should increase.
  - P2 The proportion of households with no child health expenditures should decrease.
  - P3 Health-seeking behavior in case of other diseases should increase.
Outline

Model

Data

Empirical Strategy

Results

Robustness

Conclusion
Data from Senegal

- Panel data on household expenditures on child health:
  - "Poverty and Family Structure" (PSF)
  - Nationally representative panel with 2 waves: 2006 and 2011.
  - Health and non-health expenditures at a disaggregated level ("cell").
  - Unit: all children in mother’s cell.
  - Follow 1,594 cells in 1,118 households

- Repeated cross-sections on child health status:
  - Demographic and Health Surveys in 2005 and 2010.
  - Nationally representative.
  - Health-seeking behavior in case of diarrhea, cough and fever for children under 5.
  - 8,466 children.

- Geographical data on malaria prevalence:
  - Malaria Atlas.
  - Prevalence of the disease before Roll-Back Malaria.
Outline

Model

Data

Empirical Strategy

Results

Robustness

Conclusion
Difference-in-Difference

- Compare the evolution of child health expenditures:
  - Before and after the introduction of subsidies in 2009.
  - Between malarious and non-malarious regions.
- Similar strategy in Bleakley (AEJ: Applied, 2010).
- Identification assumption:
  - In the absence of *malaria*, the evolution of health expenditures would have been the same for all households.
  - Makes no sense to look at pre-trends. Cannot look at "post-trends" because no eradication.
  - Account for changes in composition with mother fixed effects.
  - Examine trends in other determinants of child health expenses: total income, access to health and child morbidity.
Temporal variation

Amounts spent on anti-malaria programs (World Malaria Report, 2015).

- **2009**: first nationwide distribution of ITNs:
  - 6 millions bednets.
  - Price decreased from 10-12 to 0-1 euro.
  - Coverage doubled from 20% in 2006 to 40% in 2010.
- **2010**: ACT become free for all ages in public health facilities.
Spatial variation

Proportion of infected children in 2000 (Malaria Atlas)

National average = 24% → High / Low malaria prevalence
Spatial variation in our sample

Malaria prevalence and geographical distribution of PSF clusters

Source: PSF data
We define as high (resp. low) malaria prevalence clusters, clusters whose malaria prevalence in 200 was above (resp. below) the national average (24%).

Robustness

Conclusion
Alternative stories

Our results are not driven by differential trends in:

- Total income
- Health infrastructure
- Other child health campaigns
- Rainfall
- Child morbidity
- Between rural and urban areas
Robustness

Other robustness tests:
- Run the regression at the child level
- Heterogeneity by age
- Control for sibship structure and migration
- Exploit variation in campaigns intensity
- Account for attrition
Price or information?

Main mechanism is probably subsidies rather than information.

- Demand for bednets sensitive to price, not to framing (Dupas, 2009)
- Cross-disease effect hard to explain with imperfect information.
- Switchers are in the middle of the income distribution
- Response is not different for mothers targeted by information campaigns
Outline

Model

Data

Empirical Strategy

Results

Robustness

Conclusion
Conclusion

- Parental investments in child health have increased in response to anti-malaria interventions in Senegal.
  - At the intensive and extensive margins.
  - Against malaria as well as other diseases.
- Patterns consistent with an economic model of health investments under competing mortality risks.
- Malaria has long prevented parental investment in child health and heavy subsidies proved to be necessary to alleviate this constraint.
- Further research is needed to investigate the implications for fertility choices.

Data: PSF Panel. Sample in (5) & (6): Mothers residing in the same geographical district in both waves. Differences-in-differences regression with mother fixed-effects. Linear probability model.
Dep var in (1), (3) & (5): Health expenditures per capita for children in mother’s cell (thousands of CFA francs). Dep var in (2), (4) & (6): Dummy for no health expenditures for any child in the mother’s cell.
Controls included in (3) & (4): average age of children, number of children and share of children under 5
Standard errors, in (), are clustered at the mother level.
* p ≤ 0.1, ** p ≤ 0.05, *** p ≤ 0.01.

Mother FE               | Yes              | Yes          |
N                       | 1717             | 1717         |
Mean of dep. var. in low $\Delta$ in ITN use areas in 2006 | 2.62 | 0.73 |
Mean of dep. var. in high $\Delta$ in ITN use areas in 2006 | 1.55 | 0.71 |

Data: PSF Panel. Sample restricted to high malaria prevalence areas. Difference-in-difference regression with mother fixed effects. Linear probability model. Dep var: (1) Health expenditures per capita for children in mother’s cell (thousands of CFA francs). (2): Dummy for no health expenditures for any child in the mother’s cell. High $\Delta$ in ITN use: dummy equal to one if the average ITN use variation between 2006 and 2011 within the cluster of observation was higher than the national average (+20pp). Standard errors, in ( ), are clustered at the mother level.

* $p \leq 0.1$, ** $p \leq 0.05$, *** $p \leq 0.01$.

<td>340</td>
</tr>
</tbody>
</table>

Data: PSF Panel. Table constructed on the balanced sample of mothers. Mean of total cell consumption level in the last 12 months, in thousands of CFA Francs. "Never invest" (resp. "Always Invest") are cells with zero spending (resp. some spending) on child health in both waves. "Switchers" are cells with zero spending in the first wave and some spending in the second wave: they started to invest in child health between the two waves. P-values of the difference in means: (1)-(2) : p-value = 0.49 ; (2)-(3) : p-value = 0.01 ; (1)-(3) : p-value < 0.01.
The figure shows the estimated difference-in-difference by income level. Specifically, the graph plots the following equation: \( y = -5.951 + 0.037x - 0.000015x^2 \) where \( x \) ranges from the minimum to the maximum values of total annual consumption levels observed in PSF1 (excluding top 1% outliers). The coefficients are obtained by interacting Post and Post \( \times \) High Prevalence with Income and Income\(^2\).

Mother FE: Yes

N: 2749

Mean of dep. var. in low prevalence areas in 2006: 5.99, 0.54, 6.42, 0.59

Mean of dep. var. in high prevalence areas in 2006: 1.74, 0.69, 0.84, 0.67

Data: PSF Panel. Sample restricted to mothers residing in the same geographical district in both waves.

Columns (1) & (2): Sample of mothers of children under 5 or pregnant women, at time of the 2009 campaign. These mothers were targeted specifically by information campaigns.

Columns (3) & (4): Sample of other mothers.

Differences-in-differences regression with mother fixed effects. Linear probability model.

Dep var: (1) & (3) Health expenditures per capita for children in mother’s cell (thousands of CFA francs). (2) & (4): Dummy for no health expenditures for any child in the mother’s cell.

Standard errors, in (), are clustered at the mother level.

* p ≤ 0.1, ** p ≤ 0.05, *** p ≤ 0.01.
