Factory Employment and Fertility Decisions: Field Experimental Evidence from Ethiopia

Sandra K. Halvorsen
Norwegian School of Economics
Chr. Michelsen Institute

UNU-WIDER Seminar Series
27 March 2019
Motivation

Industrialisation has potentially large impacts on several developmental goals:

- Economic growth and trade
- Job creation
- Poverty reduction
- Increased *female* labor force participation
  - Income (?)
  - Fertility decisions (?)
  - Women’s empowerment (?)
Impacts of increased female labor force opportunities in manufacturing industries in developing countries

- Amin et al. (1998); Atkin (2009, 2016); Blattman and Dercon (2018); Heath (2014); Heath and Mobarak (2015); Kabeer (2002); Kagy (2017); Majlesi (2016); Sivasankaran (2014).

Impact of female employment on fertility and empowerment (household decision-making)

- Anderson and Eswaran (2009); Dharmalingam and Morgan (1996); Getahun and Villanger (2017); Jensen (2012); Van den Broeck and Maertens (2015).
Experiments

Studies using experimental design to investigate impacts of female employment
Experiments

Studies using experimental design to investigate impacts of female employment

- Jensen (2012)
  - Randomizes recruitment services for women in the BPO industry by villages in India.
  - He finds higher female labor supply and postschool training, higher age of marriage and first childbearing, increased aspirations for careers, and increased investment in younger girls.

- Blattman and Dercon (2018)
  - Randomize entry-level applicants in the manufacturing industry into industrial job, entrepreneurship program, or control group in Ethiopia.
  - They find little impact of industrial jobs on employment and wages, and increases in serious health problems. The entrepreneurial program provided better outcomes by raising earnings and providing steady working hours.
Experiments

Studies using experimental design to investigate impacts of female employment

► Jensen (2012)
  ▶ Randomizes recruitment services for women in the BPO industry by villages in India.
  ▶ He finds higher female labor supply and postschool training, higher age of marriage and first childbearing, increased aspirations for careers, and increased investment in younger girls.

► Blattman and Dercon (2018)
  ▶ Randomize entry-level applicants in the manufacturing industry into industrial job, entrepreneurship program, or control group in Ethiopia.
  ▶ They find little impact of industrial jobs on employment and wages, and increases in serious health problems. The entrepreneurial program provided better outcomes by raising earnings and providing steady working hours.
Our Contribution

- The first paper to study employment effects on fertility by randomization on individual level.
  - Experimental design to circumvent the problems of endogeniety in the female employment - fertility relationship.
  - Survey all women in the study on an individual level including a large set of questions to investigate mechanisms.
- A different and larger geographical area than many of the earlier studies.
- A different sample, only including already married, but still young, women, which is an important group with regards to family planning policy.
Female labor supply is expected to affect fertility through three channels:

- **Income effect**

- **Substitution effect**

- **Empowerment effect**
  - Chiappori and others on collective models.
The Female Labor Supply and Fertility Relationship

In a developing country context these channels may be weaker or stronger than in industrialized countries:

▶ Jobs may be more compatible with childcare.
▶ Closer networks allowing for more responsibility sharing of childcare.
▶ Preference for many children.
▶ Access to contraceptives may be limited.
The Context
Women’s labor force participation and fertility

Source: Ethiopia DHS (2016)
The Context

The manufacturing industry in Ethiopia

- The development of the manufacturing sector plays a considerable role for the implementation of Ethiopia’s vision to become middle income country and top light manufacturing hub by 2025.
The Context
The manufacturing industry in Ethiopia

- The development of the manufacturing sector plays a considerable role for the implementation of Ethiopia’s vision to become middle income country and top light manufacturing hub by 2025.
- Since 2004, Ethiopia has experienced high economic growth, averaging 10.6% GDP growth annually. The manufacturing sector’s value added as share of GDP has remained relatively stable at 3.5 - 5.5%. (Source: World Bank national accounts data)

- During the 2016/2017 fiscal year, 1.7 million jobs were created in the Ethiopian manufacturing industry. (Source: Xinhua, 04/2018)
Experimental design
Job randomization

- 30 factories in five regions
- Job offer randomization to eligible married women
- Baseline + three follow-up surveys
- Sample size: 1460
  - Follow-up 1: 1228
  - Follow-up 2: 800 (not completed)
- Balanced sample
- Treatment not predictive of attrition

The Factories

- Medium and large factories
- Textiles, apparel, shoes, cosmetics, and plastics
- Starting monthly wage 600-680 ETB (70-80 International $ at 2016 PPP terms)
- Women primarily work at the floor or as floor managers
Sample

Descriptives

- 24 years old
- 9.3 years of education
- 93% are married
- 67% have ever given birth
- 1.2 children on average
- Desired lifetime fertility is 4 children
- No difference in income by treatment group
  - Respondent’s income last twelve months: 4 200 ETB
    (480 International $ at 2016 PPP terms)
  - Husband/partner’s income last twelve months: 30 500 ETB
    (3 500 International $ at 2016 PPP terms)
- No difference in ever had a job before
Estimation Strategy

Intention-to-treat

\[ Y_i = \beta_0 + \beta_1 T_i + \gamma X_i + b_l + \epsilon_i \]  

(1)

Local Average Treatment Effect

\[ Z_i = \beta_0 + \beta_1 T_i + \gamma X_i + b_l + \epsilon_i \]  

(2)

\[ Y_i = \beta_0 + \beta_1 \hat{Z}_i + \gamma X_i + b_l + \epsilon_i \]  

(3)

\( Y_i \) = Currently pregnant or had a baby since baseline (0/1); Lifetime wanted number of children.  
\( T_i \) = Treatment status by randomization.  
\( X_i \) = Set of baseline control variables: Pregnant at baseline, Age, religion, education, number of household members, total household income last six months, dummy indicating whether respondent had any wage job the last six months, lifetime wanted fertility.  
\( b_l \) = Block fixed effect based on randomization rounds.  
\( Z_i \) = Having had any formal wage job since baseline.

Income channel
Correlations between income and number of children at baseline

Figure 1: Total household income and number of children at baseline

Notes: Binscatter, quadratic fitted line, controlling for wife and husband’s age and education.
Income channel
Correlations between income and number of children at baseline

**Figure 2:** Total wife’s income and number of children

**Figure 3:** Total husband’s income and number of children

*Notes:* Binscatter, quadratic fitted line, controlling for wife and husband’s age and education.
Income channel

- Number of children in positively correlated with total household income and with husband’s income.
- Number of children is, however, negatively correlated with wife’s earned income.
- It is therefore uncertain whether we would expect a positive or negative effect from the treatment of receiving a job offer in the manufacturing industry.
Employment opportunities increase women’s *opportunity cost* of staying outside the labor market.

- Median monthly salary in the factories is ETB 1000 (115 International $ at 2016 PPP terms).
- At baseline 1/3 had ever had a formal salaried job before.
- Total household monthly income (median) at baseline was ETB 2600, thus an income of ETB 1000 would be a considerable contribution.
The salary of the last job at baseline is however not correlated with number of children.

Figure 4: Respondent’s wage per month in the last job and number of children

Notes: Binscatter, quadratic fitted line, controlling for wife and husband’s age and education.
Although low levels of salary, the potential earnings from accepting a job offer in the factory would make a considerable contribution to the household total income.

Thus we would expect a *negative* effect from the treatment of receiving a job offer in the manufacturing industry.

However, in our sample the number of children is not correlated with the respondents’ previous salary at baseline.
Household decision-making power

Follow-up 1

Treatment effects on household decision-making
First follow-up, OLS

-0.05
0.05

Empowerment index
What to do if a child falls sick
To have children
To earn money outside the house
The use of the wife's income
Purchase of small daily food purchases
Large purchases of assets
To open a bank account or borrow money

Send or not send children to school
What to do if she falls sick
Which family planning methods to use
To visit your family or relatives
The use of the husband's income
Purchase of bulk or expensive food
Purchase of children clothing
To start a new business

OLS regressions, baseline control variables include: baseline outcome variable, age, religion, education, number of household members, total household income last six months, dummy indicating whether respondent had any wage job the last six months, and block fixed effects.
Household decision-making power

Follow-up 2

Treatment effects on household decision-making
Second follow-up, OLS

-0.05
0.05

Empowerment index
What to do if a child falls sick
To have children
To earn money outside the house
The use of the wife's income
Purchase of small daily food purchases
Large purchases of assets
To open a bank account or borrow money

Send or not send children to school
What to do if the she falls sick
Which family planning methods to use

Purchase of children clothing
To start a new business

OLS regressions, baseline control variables include: baseline outcome variable, age, religion, education, number of household members, total household income last six months, dummy indicating whether respondent had any wage job the last six months, and block fixed effects.
Summary

▶ We find that female entry-level applicants who were randomly assigned to receive a job offer have on average 42% higher income after six months, and 13% higher income after one year.

▶ There are no differences in fertility by treatment group, however, the treatment group seems to postpone childbearing a few months.

▶ There is no difference by treatment on wanted lifetime fertility.

▶ The treatment did not affect household decision-making.

▶ Theoretically, and based on our descriptive data, it is not clear how employment will affect fertility in the long run.
